# An algorithm for computing the Shapley Value 

Abdelkrim Araar and Jean-Yves Duclos

January 12, 2009

## 1 The Shapley Value

Consider a set $N$ of $n$ players that must divide a given surplus among themselves. The players may form coalitions (these are subsets $S$ of $N$ ) that appropriate themselves a part of the surplus and redistribute it between their members. We denote the number of players in subset $S$ by $s$. The function $v(S)$ is assumed to determine the coalition force, i.e., which surplus can be divided without resorting to an agreement with the outsider players. The question to resolve is: How can the surplus be divided between the $n$ players? According to the Shapley value, the surplus to be allocated to player $k$, denoted by $e_{k}$, is given by

$$
\begin{equation*}
e_{k}=\sum_{\substack{S \subset N \\ s \in\{0, n-1\}}} \frac{s!(n-s-1)!}{n!} m v(S, k) \tag{1}
\end{equation*}
$$

where

$$
\begin{equation*}
m v(S, k)=(v(S \cup\{k\})-v(S)) \tag{2}
\end{equation*}
$$

The term $m v(S, k)$ is the marginal value that player $k$ generates after his adhesion to a coalition $S$. Because the order of the players in a coalition $S$ does not affect the contribution of the player $k$ once he has adhered to the coalition, the number of calculations of $m v(S, k)$ needed in (1) is $2^{n}$, since we need to compute $m v(S, k)$ with and without each of the $n$ players.

## 2 A Shapley algorithm

The algorithm presented below explains how we may estimate the contribution of each player (or factor) in $N$ to $v(N)$. It uses three steps.

## Step 1: Constructing a basic Shapley matrix B

Each row of $\mathbf{B}$ contains a distinct subset $S_{l}$ of factors, $l \in\left\{1,2, \ldots, 2^{n}\right\}$. The number of columns is $n$ and that of rows is $2^{n}$. Let $\rho_{k}=2^{n-k}$.

To illustrate the algorithm, we set $n=5$. The matrix $\mathbf{B}$ then looks like Figure 3. Each line $l$ shows the factors that must be included in $S_{l}$ for the computation of $v\left(S_{l}\right)$. The matrix $\mathbf{B}$ is self-explanatory. Its first row $S_{1}=\{1\}$ says that $v$ must first be computed only with factor 1 ; its second row says that $v$ must then be computed with factors 1 and 2 ; and so on, until all possible subsets of $N$ have been considered. For completeness, Steps 1.a-1.d also provide a more detailed algorithm.
1.a: Constructing the first column $c_{1}$ of matrix $\mathbf{B}$.

- Initialize values of the first column to 1 in positions 1 to $\rho_{1}$. For instance, for $n=5$, the first column takes the value 1 from level 1 to 16 .
- Initialize values of the first column to 2 in $\rho_{1}+1$ to $\rho_{1}+\rho_{2}$.
- Initialize values of the first column to $k$ in $\sum_{j=1}^{k-1} \rho_{j}+1$ to $\sum_{j=1}^{k} \rho_{j}$.
- Continue the initialization until $k=n$ (see values of the first column in Figure 1).

## 1.b: Constructing the second column $c_{2}$

- Copy values of $c_{1}$ in $c_{2}$ with the following structure:

| from column $c_{1}$ in: |  |  | to column $c_{2}$ in: |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\rho_{1}+1$ | to | $\rho_{0}$ | 2 | to | $\rho_{1}+1$ |
| $\rho_{1}+\rho_{2}+1$ | to | $\rho_{0}$ | $\rho_{1}+2$ | to | $\rho_{1}+\rho_{2}+1$ |
| $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ |
| $\sum_{j=1}^{k} \rho_{j}+1$ | to | $\rho_{0}$ | $\sum_{j=1}^{k-1} \rho_{j}+2$ | to | $\sum_{j=1}^{k} \rho_{j}+1$ |

- Continue until $k=n$ (see column $c_{2}$ in Figure 1). Note the concordance of the values between the first and the second columns, emphasized in gray shading.
1.c: Constructing the remaining columns
- Use the same mapping of $c_{1} \rightarrow c_{2}$ for $c_{2} \rightarrow c_{3}$.
- Continue until $c_{n-1} \rightarrow c_{n}$. At the end of this process, a matrix similar to Figure 2 is obtained for $n=5$.

## 1.d: Repositioning values

From the matrix obtained in 1.c, we generate the basic Shapley matrix B, where each value is moved to its respective column at row level. For instance, the value of the fourth column in the sixth row equals 5 and must be moved to the fifth column in that same row. The new matrix is identical to Figure 3 for $n=5$.

## Step 2: Constructing a Shapley matrix $\mathbf{M}$ of coefficients

Denote the number of factors that appear in row $l$ by $g_{l}$, and let $\bar{g}_{l}=n-g_{l}$. We generate two $2^{n} \times 1$ vectors $\Sigma$ and $\bar{\Sigma}$ and set their members respectively to $s_{l}=\max \left(0, g_{l}-1\right)$ and $\bar{s}_{l}=\max \left(0, \bar{g}_{l}-1\right)$ at position $l$ (see Figure 4). Let the indicator $u_{l, k}=1$ if factor $k \in S_{l}$ (the element $b_{l, k}$ of matrix B is a non-missing value) and zero otherwise. Let $\bar{u}_{l, k}=u_{l, k}-1$. Elements of the matrix $\mathbf{M}$ are defined as

$$
\begin{equation*}
m_{l, k}=\frac{u_{l, k} s_{l}!\left(n-s_{l}-1\right)!+\bar{u}_{l, k} \bar{s}_{l}!\left(n-\bar{s}_{l}-1\right)!}{n!} . \tag{3}
\end{equation*}
$$

Note that the matrices B and M can be computed without any knowledge of the function $v$.

## Step 3: Estimating the contributions of factors.

3.1: Estimating the contribution of factor $k$ according to the level of the introduction of that factor.
Let the $2^{n} \times 1$ vector $I_{k, z}$ be defined to estimate the average contribution of factor $k$ once it is introduced at level $z \in[1, \ldots, n]$. Thus, $I_{1,2}$ will serve to estimate the second-level contribution of factor 1 , obtained when factor 1 is introduced to compute the function $v(\cdot)$ after another factor has already been included. At position $l \in\left\{1,2^{n}\right\}$, the element of $I_{k, z}$ equals $m_{l, k}$ if $u_{l, k}=1$ and $g_{l}=z$ or if $\bar{u}_{l, k}=1$ and $\bar{g}_{l}=z-1$, and is set to zero otherwise. The contribution of factor $k$ at level $z$ is then equal to $I_{k, z}^{\prime} \mathbf{V}$.

## 3.2: Estimating the elements of the Shapley decomposition.

Let the elements $v_{l}$ of the $1 \times n$ vector $\mathbf{V}=\left(v_{1}, \ldots, v_{2^{n}}\right)$ be given by function $v\left(S_{l}\right)$, where $S_{l}$ is row $l$ of matrix $\mathbf{B}$. Let the $1 \times n$ vector $\mathbf{E}$ be given by $\mathbf{E}=\mathbf{V}^{\prime} \mathbf{M}$. Element $e_{k}$ of $\mathbf{E}$ gives the Shapley contribution of factor $k$ to $v(N)$, as defined also in (1).
